

Status with ESO Followup

Few Notes prepared in collaboration
with Luigi Stella

New Orleans - September 7 2004

Triggers - RRM

- As already stated the groups interested in GRBs in Europe in collaboration with ESO were able to set up a RRM procedure that allows the VLT to 1) stop the on going program (w/o losing the data being collected), 2) point the coordinates of the trigger automatically received following a predetermined priority program, 3) start operation on a new target (assuming no time is lost for the target ID) in **6.5 Minutes**. The programs approved are ready for fast activation.
- Other observations will be carried out according to the proposals submitted by different groups

New Orleans - September 7 2004

Policy – ESO – See Web

- Exceptionally during P75 ESO will consider extending the ToO observing time (up to 5% now) to accommodate an expected increase of GRB triggers.
- Following an expected substantial in the number of detected GRB events and the Robotic Telescopes REM and Tarot becoming operational ESO started to offer ... UVES .. FORS1 .. FORS2 ... in Rapid Response Mode (RRM).
 - No change of instrument is accepted in the automatic RRM
 - Activation during Service Mode runs only
 - No proprietary data period.
 - A case can be made by the PI of the proposal for a 3 months proprietary periodo.

New Orleans - September 7 2004

Organization – GRBs at ESO

- Much still needs to be done in the communication system within ESO staff and the guidelines to be received by the OPC (TAC).
- The new OPC guidelines tend to prefer well focused single science argument rather than favor a more general science approach needing eventually different observing strategies. See also Call P75.
- This approach could lead to confusion and a rather heavy load for the Staff of Paranal who is not particularly happy of being overloaded by different and too many triggers. Potential overlap and not clear triggering selection procedure.
- We feel we need better procedures and probably changes need to be further discussed within the ESO GRB community.
- The way may be that to organize the follow up more or less the way we organize the activity with the Swift Satellite.
- **Any special strategy from the Ground Based US Large Telescopes?**

New Orleans - September 7 2004

Others

- TNG Canaries Islands – we may be able to set up a sensible program. TBD.
- Chandra: we understand it may be possible to implement a faster response time. Anybody know about it?
- XMM: The project already improved the response time of the spacecraft and, especially thanks to some of the results obtained, we hope that Fred Jansen will be willing to invest more time in the GRBs.
- INTEGRAL: We all know about it and recently gave a reasonable number of triggers (obviously we have a Galactic Plane bias). See Mereghetti.

New Orleans - September 7 2004

GRB 031203 - INTEGRAL

New Orleans - September 7 2004

The 031203 SN

Spectra of the underlying SN after subtracting the spectrum taken On March 3rd from the spectra of the 20th and 30th of December.

The dotted lines refer to SN 1998 bw taken 2 days before and 7 days after the Maximum in V light (13.5 and 23.5 days after the GRB), Palat et al. 2001, Ap.J. 555, 900.

The REM Observatory:

The REM/ROS Team

**Part of a more general presentation prepared by
Filippo Maria Zerbi**

General Presentation

REM

A fast moving telescope ...

- Alt-az 60 cm f/8 RC silver-coated
- 2 Nasmyth foci (one idle)
- 60 deg 5 sec – to any α, δ in 60 sec

REM

... with a high throughput NIR Camera...

- 10x10 am² FoV
- 1.2 arc pixel scale (diff.limited)
- 0.9-2.3 microns (Z', J, H, Ks)
- 512x512 HgCdTe chip @77 Kelvin
- Wobbling plate for dithering

... and a Visible Imaging-Spectrograph

- 10x10 am² FoV
- 0.55 arc pixel scale
- 30 bins between 0.45-0.9 μm (Amici Prism)
- 1024x1024 Marconi CCD in Apogee head

REMOS:

- Target acquisition
 - Start observation
- 5-10 s up.tr.rec.**

One Raw Image every **1.5 s**

PREPROCESS:

Sky and Bias Subtraction
flat fielding and dithering reconstruction
5 images processed in 3.7 s

One Cleaned Image
every **7.5 s**

Quick-Look Scientific pipeline

- Transient detection (SEXtractor) [**.2 s**]
- Coordinates determination [**2 s**]
- Photometry (Z'JHK) (any object in the frame above a S/N threshold) [**6 s**]

General Presentation

REM

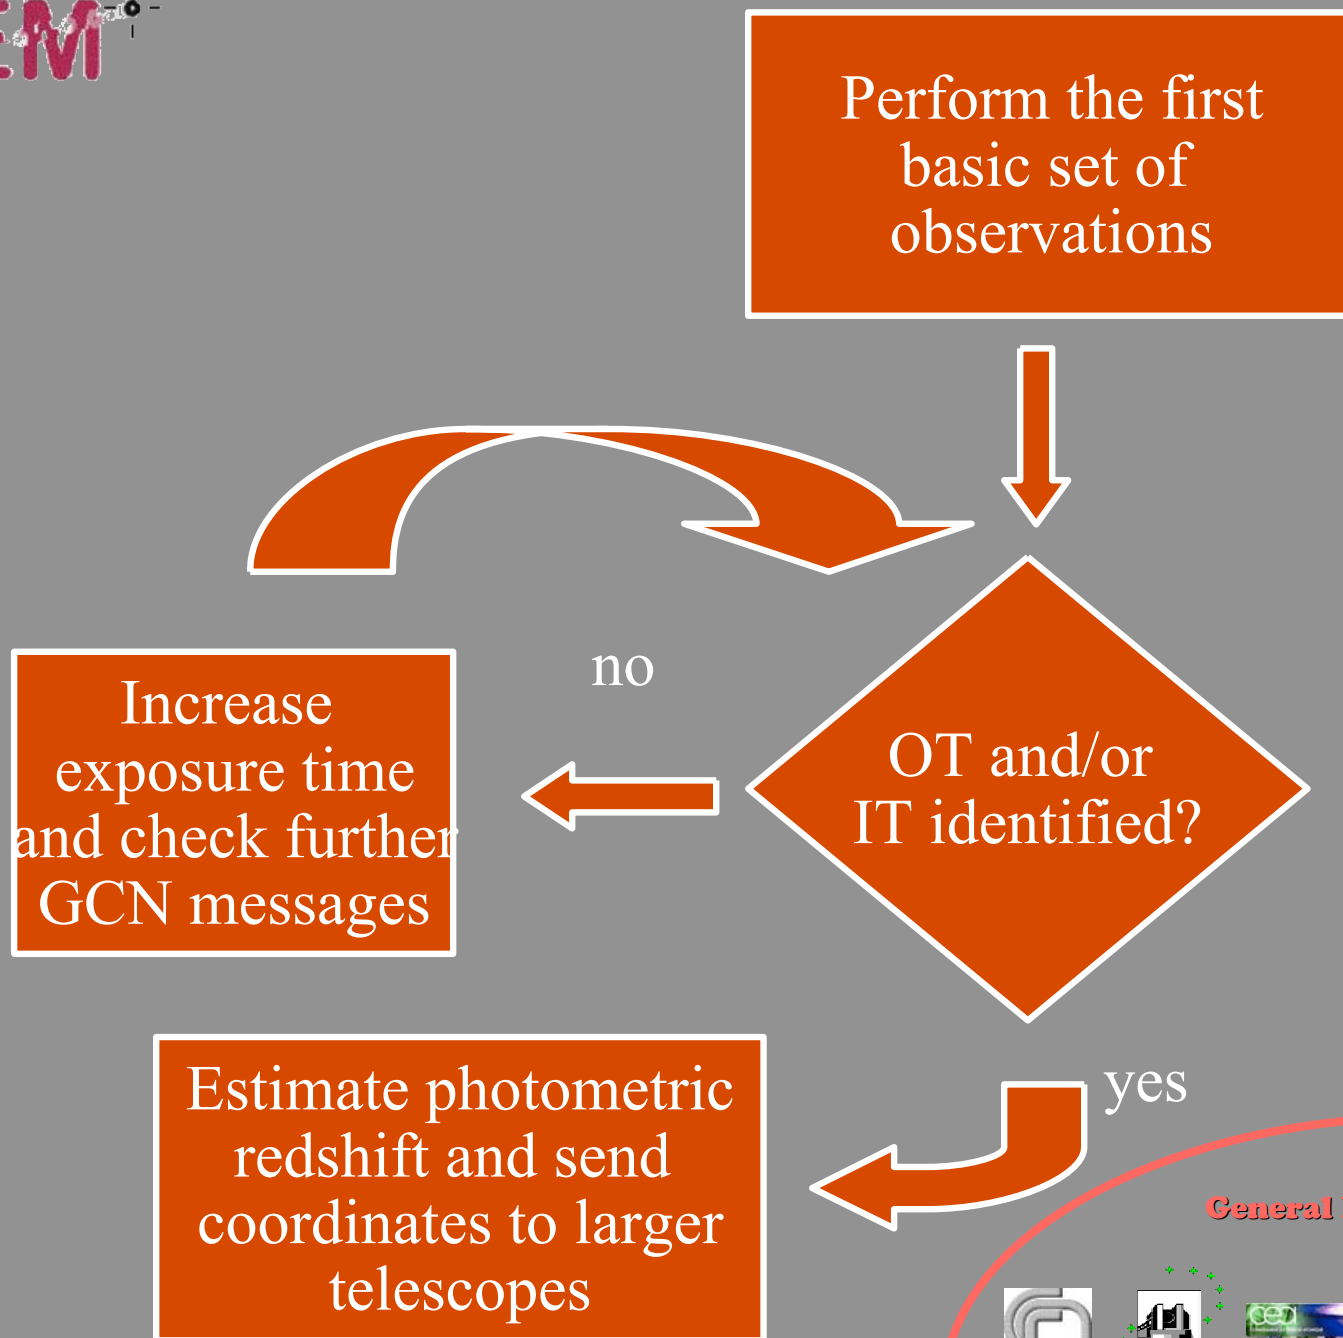

AQuA

20 sec!
The five images are reduced and a first scientific image is obtained. A second set of 5 dithered images is acquired, are subtracted and smoothed then a source detection algorithm is applied to look for variable objects.

General Presentation

General Presentation

REM

What is REM for ?

REM is conceived as a link between **transient phenomena** detected at high energy from space **AND** Large ground-based facilities on the ground → Gamma Ray Bursts

REM

Such a link is needed for:

- Transient Coordinate determination

High Energy detections have large error-boxes

- Pre-screen of transient characteristics

Cases selection for further observations

In both Cases crucial are:

- a) Coverage up to NIR
- b) Fast response

General Presentation

What SWIFT gives us is

- **Position of the GRB - [15 sec] (4 am)**
- **Position of the XT [20-70 sec] (5 as)**
- **Position of the OT [20-70 sec] (n/10 as) (if there)**
- **Color Information 0.15-0.65 μm [600 sec]**

What SWIFT does not give us

- **Position of the Red-T (above 0.65 μm) and NIR-T**

>150 trigger per year !

General Presentation

ROSS acquires 30 simultaneous calibrated data points between 0.45 and 0.9 microns

This allows to:

- **Correlate the time of the optical peaks with the distribution of Lorentz Factors in the original cataclysm.**
- **Detect the possible time dependent obscuration of optical transients associated with GRBs.**
- **Possibly detect the peak energy that goes from gamma to optical within few hours.**

General Presentation

Any possible optimization of the Space-borne trigger source will let free REM observing time

INTEGRAL-AGILE few bursts

SWIFT-HETE II more bursts but
latitude/longitude constraints

- **Housekeeping and calibration**
- **Other Observing programs**

Anywhere Rapid multi-frequency observations are needed

- 1. Multifrequency monitoring of AGNs**
- 2. Black Hole Candidates –X-ray Novae**
- 3. Flare Stars**
